Documentation: Sage appointments app

What we were asked

To build a small appointments product with two sides that share the same data. The client app is for phones: a home screen with the next visit, booking with no double booking, upcoming and past visits, and reschedule or cancel. The nutritionist dashboard shows a list with name, phone, date, time and status (Booked, Done, No-show in different colours). She can change the status, add a visit by hand, filter to today, and see everything clients book. It must load the sample data and include at least one thing that helps with no-shows.

Your approach

I built one web page with two views, Client app and Nutritionist. Both read and write the same list of appointments, so a change on one side shows on the other. The client view is phone sized and sits in the middle on a desktop. The dashboard is wider and stacks into cards on a phone. I kept the look calm: soft colours, rounded cards and a dark mode. For no-shows I added a confirm button for the client, a WhatsApp reminder button for her, and a no-show rate.

Decisions and assumptions

Sample data. The dates came in three styles and the times in four. I converted all of them to one style, for example 11:30am became 11:30 and 4 pm became 16:00. I read 24/10/2026 as day/month because there is no 24th month. Phone numbers are stored as 10 digits and shown like 98200 11111. The two Riya Shah rows have the same phone, so I treat them as one client with two visits. Meera Iyer has no phone, so it shows "No phone". I did not make up a number. All sample rows start as not confirmed.

Shared data. Both sides use one list saved in the browser (local storage). A booking on the client side shows on the dashboard and the other way round, also across two tabs of the same browser. I assumed a demo does not need a server. The limit is that two different devices do not sync. A real product would need a hosted database.

Dates. The sample rows are from 22 to 25 Oct 2026. If the app used the real date, the home screen would say "No visit planned" and the Today filter would be empty. So the app starts on 24 Oct 2026, and a banner says so. One tap on the banner switches to the real date of the device.

No login. A client is found by phone number. The demo starts as Riya. There are quick buttons to switch to other sample clients, or you can type a number.

Time slots. One slot every 30 minutes, 9:00 AM to 5:30 PM. A slot is blocked if an appointment already has that date and time, and past times are switched off. The check runs again when the client confirms.

Cancel. The brief gives only three statuses, so a cancelled visit is deleted and its slot becomes free. I did not add a fourth status.

What you added

A confirm button for the client, a WhatsApp reminder button and a no-show rate (all for the no-show problem). Also a "Past: please update" tag for old visits that are still Booked, quick client switch buttons, and a button to reset the sample data. I added them so the nutritionist's statuses stay correct and so a reviewer can test easily.

What the AI got wrong (and how you caught and fixed it)

I used Claude to build this. Three things went wrong.

1. The first version was written without being run. I tested it in a real browser (booking, same slot again, reschedule, cancel, status change, adding from the dashboard, Today filter, reload). I found no crashes.

2. With the real date, the sample visits all looked like the past, so the home screen was empty and Today showed nothing. I noticed this on first load. I fixed it with the demo date and the banner described above.

3. The AI had marked Riya's first visit as already confirmed in the sample data. This is not in the brief. I found it when I compared the loaded data to the sample table, and I changed it so every sample row starts as not confirmed.

How to run it

Open index.html in any browser. There is nothing to install. To put it online, upload the folder to GitHub and import it in Vercel with the "Other" preset. It is a plain static page.
